## Enthalpy (H)

A substance energy can be measured by Enthalpy.
Enthalpy $(H)$ is the heat transferred between the system and the surroundings during a chemical reaction carried out under constant pressure. Again, we can only measure the change in enthalpy $\Delta H$.

Enthalpy H is the total energy content of a sample at a constant pressure. The heat gained or lost by a substance is:

$$
\Delta H=q_{\mathrm{p}}=\mathrm{nC} \Delta \mathrm{~T}=\mathrm{nC}(\mathrm{~T} \text { final }-\mathrm{T} \text { initial })
$$

C is molar heat capacity : C ; $\mathrm{J} /$ mole. K , n : mole,
T: Kelvin
The units of $\Delta H \mathrm{~kJ} / \mathrm{mole}$

There are four ways to calculate enthalpy (A, B, C, D)
A) Calorimetry
B) From tables of standards values
C) Hess's Law
D) Bond energies
and also stoichiometry.

## A) Molar enthalpy change ( First Way)

Molar enthalpy change is the enthalpy change for one mole $\mathrm{n}=1$.

$$
\Delta H=C \Delta T=C(T \text { final }-T \text { initial })
$$

Heating: Endothermic: Absorb heat: $\Delta \mathrm{H}>0$.

$$
\begin{aligned}
& \mathrm{T} \text { final }>\mathrm{T} \text { initial so, } \mathrm{T} \text { final }-\mathrm{T} \text { initial }>0 \\
& \Delta \mathrm{H}=\mathrm{C} \Delta \mathrm{~T}=\mathrm{C}(\mathrm{~T} \text { final }-\mathrm{T} \text { initial })>0 .
\end{aligned}
$$

Cooling: Exothermic: Release heat: $\Delta \mathrm{H}<0$.

$$
\begin{aligned}
& \mathrm{T} \text { final }<\mathrm{T} \text { initial so, } \mathrm{T} \text { final }-\mathrm{T} \text { initial }<0 \\
& \Delta \mathrm{H}=\mathrm{C} \Delta \mathrm{~T}=\mathrm{C}(\mathrm{~T} \text { final }-\mathrm{T} \text { initial })<0 .
\end{aligned}
$$

When two substance of different temperature are in contact.
Heat gained $=$ Heat lost.

## Enthalpy is an extensive property

1) The magnitude of enthalpy is directly proportional to the amount of reactant consumed.

Example: If one mole of $\mathrm{CH}_{4}$ is burned in oxygen to produce $\mathrm{CO}_{2}$ and water, 890 kJ of heat is released to the surroundings. If two moles of $\mathrm{CH}_{4}$ are burned then $2 x 890=1780 \mathrm{~kJ}$ of heat is released.
$\mathrm{CH}_{4}(\mathrm{~g})+2 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow \mathrm{CO}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{I})+$ energy $\Delta H=-890 \mathrm{~kJ}$
So:
$2 \mathrm{CH}_{4}(\mathrm{~g})+4 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{CO}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})+$ energy $\Delta H=2(-890 \mathrm{~kJ})=1780 \mathrm{~kJ}$
2) The sign of $\Delta H$ depends on the direction of the reaction. The enthalpy change for a reaction is equal in magnitude but opposite in sign to $\Delta H$ for the reverse reaction.
Example:
$\mathrm{CH}_{4}(\mathrm{~g})+2 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow \mathrm{CO}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{I})+$ energy $\Delta H=-890 \mathrm{~kJ}$
So:
$\mathrm{CO}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{I})+$ energy $\longrightarrow \mathrm{CH}_{4}(\mathrm{~g})+2 \mathrm{O}_{2}(\mathrm{~g}) \Delta H=+890 \mathrm{~kJ}$
3) Enthalpy change depends on state:

$$
2 \mathrm{H}_{2} \mathrm{O}(\mathrm{~g}) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(\mathrm{I}) \quad \Delta H=-88 \mathrm{~kJ}
$$

## B) Hess's Law (Second Way)

Hess's Law: if a reaction is carried out in a series of steps, $\Delta H$ for the reaction is the sum of $\Delta H$ for each of the steps.

The $\Delta H$ is independent of the number of steps and the nature of the path.
Step 1: $\mathrm{CH}_{4}(\mathrm{~g})+2 \mathrm{O}_{2} \longrightarrow \mathrm{CO}_{2}+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{g}) \quad \Delta H_{l}=-802 \mathrm{~kJ}$
Step 2: $2 \mathrm{H}_{2} \mathrm{O}(\mathrm{g}) \longrightarrow 2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \quad \Delta H_{2}=-88 \mathrm{~kJ}$

Step 1+2: $\mathrm{CH}_{4}(\mathrm{~g})+2 \mathrm{O}_{2} \longrightarrow \mathrm{CO}_{2}(\mathrm{~g})+2 \mathrm{H}_{2} \mathrm{O}(\mathrm{l}) \Delta H_{l+2}=-890 \mathrm{~kJ}$

## $\Delta H$ is sensitive to the states of the reactants and products.

Hess's law allows us to calculate enthalpy data for reactions which are difficult to carry out directly.

## C) Using standard enthalpy of formation (Third Way)

Using Enthalpy of Formation to Calculate Enthalpies of Reaction

$$
\Delta H^{\mathrm{o}_{\mathrm{rxn}}}=\Sigma \mathrm{n} \Delta H^{\mathrm{o}_{\mathrm{f}}} \text { (products) }-\Sigma \mathrm{m} \Delta H^{\mathrm{o}_{\mathrm{f}}} \text { (reactants) }
$$

Where n and m are the stoichiometric coefficients.
Example:
Calculate the $\Delta H^{0_{\mathrm{rxn}}}$ for:

$$
\mathrm{C}_{3} \mathrm{H}_{8}(\mathrm{~g})+5 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 3 \mathrm{CO}_{2}(\mathrm{~g})+4 \mathrm{H}_{2} \mathrm{O}(\mathrm{l})
$$

$\Delta H^{0_{\mathrm{rxn}}}=3(-393.5 \mathrm{~kJ})+4(-285.8 \mathrm{~kJ})-1(-103.85 \mathrm{~kJ})-5(0)=-2220 \mathrm{~kJ}$.

| Compound | $\Delta H_{\text {f }}^{\circ}(\mathrm{kJ} / \mathrm{mol})$ |
| :---: | :---: |
| $\mathrm{NH}_{3}(\mathrm{~g})$ | -46 |
| $\mathrm{NO}_{2}(\mathrm{~g})$ | 34 |
| $\mathrm{H}_{2} \mathrm{O}(l)$ | -286 |
| $\mathrm{Al}_{2} \mathrm{O}_{3}(\mathrm{~s})$ | -1676 |
| $\mathrm{Fe}_{2} \mathrm{O}_{3}(s)$ | -826 |
| $\mathrm{CO}_{2}(\mathrm{~g})$ | -394 |
| $\mathrm{CH}_{3} \mathrm{OH}(l)$ | -239 |
| $\mathrm{C}_{8} \mathrm{H}_{18}($ l $)$ | -269 |

## Example 2:

The combustion reaction for methanol is

$$
2 \mathrm{CH}_{3} \mathrm{OH}(l)+3 \mathrm{O}_{2}(\mathrm{~g}) \longrightarrow 2 \mathrm{CO}_{2}(g)+4 \mathrm{H}_{2} \mathrm{O}(l)
$$

Using the standard enthalpies of formation from Table 6.2 and Equation (6.1), we have

$$
\begin{aligned}
\Delta H_{\text {reaction }}^{\circ}= & 2 \times \Delta H_{\mathrm{f}}^{\mathrm{\circ}} \text { for } \mathrm{CO}_{2}(g)+4 \times \Delta H_{\mathrm{f}}^{\mathrm{\circ}} \text { for } \mathrm{H}_{2} \mathrm{O}(l)- \\
& 2 \times \Delta H_{\mathrm{f}}^{\mathrm{\circ}} \text { for } \mathrm{CH}_{3} \mathrm{OH}(l) \\
= & 2 \times(-394 \mathrm{~kJ})+4 \times(-286 \mathrm{~kJ})-2 \times(-239 \mathrm{~kJ}) \\
= & -1454 \mathrm{~kJ}
\end{aligned}
$$

| TABLE 6.2 <br> of Formation <br> Compounds at <br> Cor Several |
| :--- | ---: |
| Compound |

## D) Bond Enthalpies and the Enthalpies of Reactions (Fourth Way)

We can use bond enthalpies to calculate the enthalpy for a chemical reaction. In a chemical reaction bonds need to be broken and then new bonds form. The enthalpy of the reaction is given by:
$\Delta H_{\mathrm{rxn}}=$ energy required to break bonds - energy released when bonds form

$$
\Delta H_{\mathrm{rxn}}=\Sigma \mathrm{n} D(\text { bonds broken })-\Sigma \mathrm{m} D(\text { bonds formed })
$$

## TABLE 8.4 Average Bond Energies ( $\mathbf{k J} / \mathrm{mol}$ )

| Single Bonds |  |  |  |  |  |  | Multiple Bonds |
| :--- | :--- | :--- | :--- | :--- | :--- | :--- | ---: |
| $\mathrm{H}-\mathrm{H}$ | 432 | $\mathrm{~N}-\mathrm{H}$ | 391 | $\mathrm{I}-\mathrm{I}$ | 149 | $\mathrm{C}=\mathrm{C}$ | 614 |
| $\mathrm{H}-\mathrm{F}$ | 565 | $\mathrm{~N}-\mathrm{N}$ | 160 | $\mathrm{I}-\mathrm{Cl}$ | 208 | $\mathrm{C} \equiv \mathrm{C}$ | 839 |
| $\mathrm{H}-\mathrm{Cl}$ | 427 | $\mathrm{~N}-\mathrm{F}$ | 272 | $\mathrm{I}-\mathrm{Br}$ | 175 | $\mathrm{O}=\mathrm{O}$ | 495 |
| $\mathrm{H}-\mathrm{Br}$ | 363 | $\mathrm{~N}-\mathrm{Cl}$ | 200 |  |  | $\mathrm{C}=\mathrm{O}^{*}$ | 745 |
| $\mathrm{H}-\mathrm{I}$ | 295 | $\mathrm{~N}-\mathrm{Br}$ | 243 | $\mathrm{~S}-\mathrm{H}$ | 347 | $\mathrm{C} \equiv \mathrm{O}$ | 1072 |
|  |  | $\mathrm{~N}-\mathrm{O}$ | 201 | $\mathrm{~S}-\mathrm{F}$ | 327 | $\mathrm{~N}=\mathrm{O}$ | 607 |
| $\mathrm{C}-\mathrm{H}$ | 413 | $\mathrm{O}-\mathrm{H}$ | 467 | $\mathrm{~S}-\mathrm{Cl}$ | 253 | $\mathrm{~N}=\mathrm{N}$ | 418 |
| $\mathrm{C}-\mathrm{C}$ | 347 | $\mathrm{O}-\mathrm{O}$ | 146 | $\mathrm{~S}-\mathrm{Br}$ | 218 | $\mathrm{~N}=\mathrm{N}$ | 941 |
| $\mathrm{C}-\mathrm{N}$ | 305 | $\mathrm{O}-\mathrm{F}$ | 190 | $\mathrm{~S}-\mathrm{S}$ | 266 | $\mathrm{C} \equiv \mathrm{N}$ | 891 |
| $\mathrm{C}-\mathrm{O}$ | 358 | $\mathrm{O}-\mathrm{Cl}$ | 203 |  |  | $\mathrm{C}=\mathrm{N}$ | 615 |
| $\mathrm{C}-\mathrm{F}$ | 485 | $\mathrm{O}-\mathrm{I}$ | 234 | $\mathrm{Si}-\mathrm{Si}$ | 340 |  |  |
| $\mathrm{C}-\mathrm{Cl}$ | 339 |  |  | $\mathrm{Si}-\mathrm{H}$ | 393 |  |  |
| $\mathrm{C}-\mathrm{Br}$ | 276 | $\mathrm{~F}-\mathrm{F}$ | 154 | $\mathrm{Si}-\mathrm{C}$ | 360 |  |  |
| $\mathrm{C}-\mathrm{I}$ | 240 | $\mathrm{~F}-\mathrm{Cl}$ | 253 | $\mathrm{Si}-\mathrm{O}$ | 452 |  |  |
| $\mathrm{C}-\mathrm{S}$ | 259 | $\mathrm{~F}-\mathrm{Br}$ | 237 |  |  |  |  |
|  |  | $\mathrm{Cl}-\mathrm{Cl}$ | 239 |  |  |  |  |
|  |  | $\mathrm{Cl}-\mathrm{Br}$ | 218 |  |  |  |  |
|  | $\mathrm{Br}-\mathrm{Br}$ | 193 |  |  |  |  |  |
|  |  |  |  |  | $\mathrm{C}=\mathrm{O}\left(\mathrm{CO}_{2}\right)=799$ |  |  |

## Example 1:

Using the bond energies listed in Table 8.4, calculate $\Delta H$ for the reaction of methane with chlorine and fluorine to give Freon- $12\left(\mathrm{CF}_{2} \mathrm{Cl}_{2}\right)$.

$$
\mathrm{CH}_{4}(g)+2 \mathrm{Cl}_{2}(g)+2 \mathrm{~F}_{2}(g) \longrightarrow \mathrm{CF}_{2} \mathrm{Cl}_{2}(g)+2 \mathrm{HF}(g)+2 \mathrm{HCl}(g)
$$

## Solution:

## Reactant Bonds Broken:

$$
\begin{array}{rlrl}
\mathrm{CH}_{4}: & 4 \mathrm{~mol} \mathrm{C}-\mathrm{H} & 4 \mathrm{~mol} \times \frac{413 \mathrm{~kJ}}{\mathrm{~mol}} & =1652 \mathrm{~kJ} \\
2 \mathrm{Cl}_{2}: & 2 \mathrm{~mol} \mathrm{Cl}-\mathrm{Cl} & 2 \mathrm{~mol} \times \frac{239 \mathrm{~kJ}}{\mathrm{~mol}} & =478 \mathrm{~kJ} \\
2 \mathrm{~F}_{2}: & 2 \mathrm{~mol} \mathrm{~F}-\mathrm{F} & 2 \mathrm{~mol} \times \frac{154 \mathrm{~kJ}}{\mathrm{~mol}} & =308 \mathrm{~kJ} \\
& & \text { Total energy required } & =2438 \mathrm{~kJ}
\end{array}
$$

## Product Bonds Formed:

$$
\begin{array}{rlr}
\mathrm{CF}_{2} \mathrm{Cl}_{2}: & 2 \mathrm{~mol} \mathrm{C}-\mathrm{F} & 2 \mathrm{~mol} \times \frac{485 \mathrm{~kJ}}{\mathrm{~mol}}
\end{array}=970 \mathrm{~kJ}
$$

We now can calculate $\Delta H$ :

$$
\begin{aligned}
\Delta H & =\text { energy required to break bonds }- \text { energy released when bonds form } \\
& =2438 \mathrm{~kJ}-3632 \mathrm{~kJ} \\
& =-1194 \mathrm{~kJ}
\end{aligned}
$$

Since the sign of the value for the enthalpy change is negative, this means that 1194 kJ of energy is released per mole of $\mathrm{CF}_{2} \mathrm{Cl}_{2}$ formed.

## Example 2:

We illustrate the concept with the reaction between methane, $\mathrm{CH}_{4}$ and chlorine:

$$
\mathrm{CH}_{4}(g)+\mathrm{Cl}_{2}(g) \longrightarrow \mathrm{CH}_{3} \mathrm{Cl}(g)+\mathrm{HCl}(g)
$$

In this reaction one $\mathrm{C}-\mathrm{H}$ bond and one $\mathrm{Cl}-\mathrm{Cl}$ bond are broken while on $\mathrm{C}-\mathrm{Cl}$ bond and one $\mathrm{H}-\mathrm{Cl}$ bond are formed. (values in table 8.4 next page)

So

$$
\begin{gathered}
\Delta H_{\mathrm{rxn}}=[D(\mathrm{C}-\mathrm{H})+D(\mathrm{Cl}-\mathrm{Cl})]-[D(\mathrm{C}-\mathrm{Cl})+D(\mathrm{H}-\mathrm{Cl})=-104 \mathrm{~kJ} . \\
\text { or } \\
\Delta H_{\mathrm{r} \times \mathrm{n}}=[4 D(\mathrm{C}-\mathrm{H})+D(\mathrm{Cl}-\mathrm{Cl})]-[3 D(\mathrm{C}-\mathrm{H})+D(\mathrm{C}-\mathrm{Cl})+D(\mathrm{H}-\mathrm{Cl})=-104 \mathrm{~kJ} .
\end{gathered}
$$

The overall reaction is exothermic which means that the bonds formed are stronger than the bonds broken.

Notes:
The molar heat capacity ( C ) depends on the number of atoms.

$$
\Delta H=q_{\mathrm{p}}=\mathrm{nC} \Delta \mathrm{~T}=\mathrm{nC}(\mathrm{~T} \text { final }-\mathrm{T} \text { initial })
$$

For all metals, the molar heat capacity is around $25 \mathrm{~J} / \mathrm{K}$.mole, because it is for 1 atom only.
Water has three atoms (HO, 1 O and 2 H )). The molar heat capacity for liquid water is: $3 \times 25=75 \mathrm{~J} / \mathrm{K}$. mole. This also applies to the molar heat capacity of ionic compounds. The molar heat capacity for $\mathrm{AlCl}_{3}$ is $92 \mathrm{~J} /$ K.mole, which is almost $4 \times 25$ because $\mathrm{AlCl}_{3}$ has 4 atoms ( 1 Al and 3 Cl )

| Element | C ( $\mathrm{J} / \mathrm{K} \cdot \mathrm{mol}$ ) | Compound | C ( $\mathrm{J} / \mathrm{K} \cdot \mathrm{mol}$ ) |
| :---: | :---: | :---: | :---: |
| Aluminum, $\mathrm{Al}(\mathrm{s})$ | 24.2 | Aluminum chloride, $\mathrm{AlCl}_{3}(s)$ | 92.0 |
| Argon, $\operatorname{Ar}(\mathrm{g})$ | 20.8 | Barium chloride, $\mathrm{BaCl}_{2}(s)$ | 75.1 |
| Helium, $\mathrm{He}(\mathrm{g})$ | 20.8 | Cesium iodide, $\operatorname{CsI}(s)$ | 51.8 |
| Iron, $\mathrm{Fe}(s)$ | 25.1 | Octane, $\mathrm{C}_{8} \mathrm{H}_{18}(l)$ | 254.0 |
| Mercury, $\mathrm{Hg}(l)$ | 27.8 | Sodium chloride, $\mathrm{NaCl}(\mathrm{s})$ | 50.5 |
| Nitrogen, $\mathrm{N}_{2}(\mathrm{~g})$ | 29.1 | Water, $\mathrm{H}_{2} \mathrm{O}(\mathrm{g})$ | 36.8 |
| Silver, $\mathrm{Ag}(\mathrm{s})$ | 25.3 | Water, $\mathrm{H}_{2} \mathrm{O}(l)$ | 75.3 |
| Tungsten $\mathrm{W}(\mathrm{s})$ | 24.2 | Water, $\mathrm{H}_{2} \mathrm{O}(\mathrm{s})$ | 37.4 |

Molar heat capacity $(C)$ is related to specific heat $\left(C_{p}\right)$

$$
\begin{aligned}
& \Delta H=q_{\mathrm{p}}=\mathrm{n} \mathrm{C} \Delta \mathrm{~T}=\mathrm{m} \mathrm{c}_{\mathrm{p}} \Delta \mathrm{~T} \\
& M(\mathrm{~g} / \mathrm{mol}) \times c_{p}(\mathrm{~J} / \mathrm{K} \cdot \mathrm{~g})=C(\mathrm{~J} / \mathrm{K} \cdot \mathrm{~mol}) \\
&(\text { molar mass })(\text { specific heat })=(\text { molar heat capacity })
\end{aligned}
$$

Example: water: molar mass $18 \mathrm{~g} / \mathrm{mole}$
molar mass of water $x$ specific heat of water $=$ molar heat capacity of water

$$
18 \times 4.18=75.24
$$
